Are neutral roots in Uyghur really neutral? Experimental and structural evidence

1. Underlying contrasts

Diachronic changes can remove a surface contrast between two phonemes but maintain original phonological behavior

Proto-Inuit > Inuit: *i/ > i/, *l/ > l/ (Compton and Dresher 2011)

- In some dialects, /i/ triggers palatalization, /i/ does not

How do speakers learn and represent such patterns?

This paper looks at a specific case in Uyghur

2. Uyghur backness harmony

Basic pattern: Suffixes agree in backness with final root vowel

<table>
<thead>
<tr>
<th>vrde/-dh</th>
<th>‘type-LOC’</th>
</tr>
</thead>
<tbody>
<tr>
<td>pul-grad</td>
<td>‘money-LOC’</td>
</tr>
<tr>
<td>munbar-grad</td>
<td>‘podium-LOC’</td>
</tr>
<tr>
<td>etarp-tar/-ta</td>
<td>‘area-LOC’</td>
</tr>
</tbody>
</table>

The vowel /i/ is transparent

mägät-tir/-ta | ‘mosque-LOC’ |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>tekši-lari/ta</td>
<td>‘taxi-PL’</td>
</tr>
<tr>
<td>amlin-grad</td>
<td>‘element-LOC’</td>
</tr>
</tbody>
</table>

Neutral roots with only transparent vowels vary in suffix backness

<table>
<thead>
<tr>
<th>biz-grad</th>
<th>‘us-DAT’</th>
</tr>
</thead>
<tbody>
<tr>
<td>sir-lari/ta</td>
<td>‘secret-PL’</td>
</tr>
<tr>
<td>ilim-grad</td>
<td>‘knowledge-LOC’</td>
</tr>
<tr>
<td>sinip-tyl/ta</td>
<td>‘classroom-LOC’</td>
</tr>
</tbody>
</table>

Modern /i/ corresponds to historic /i/ and /ɯ/ (Erdal 2004)

- Roots often preserve historical behavior
- Drift towards back suffixes for less frequent words (Lindblad 1990)

3. Representing neutral roots

Covert contrast analysis (Lindblad 1990, Hahn 1991)

UR /sur-lar/ | /biii-gra/ |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Harmony sur-lar</td>
<td>biz-de</td>
</tr>
<tr>
<td>Fronting sir-lari</td>
<td>biz-dar</td>
</tr>
<tr>
<td>SR [sirlar]</td>
<td>[bizdar]</td>
</tr>
</tbody>
</table>

Lexical diacritic analysis (Mayer 2021)

UR /sir/ | /bii/- DA/ |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Harmony sir</td>
<td>biz-de</td>
</tr>
<tr>
<td>SR [sir]</td>
<td>[bizde]</td>
</tr>
</tbody>
</table>

Can we differentiate between these two analyses?

Hungarian VH has similar neutral roots

- Tongue backness in unsuffixed neutral roots is predicted by the backness of the suffixes they take (Benus and Gafos 2007)
- Phonetic contrast suggests phonemic contrast?

Can we find similar evidence in Uyghur?

This study argues against a covert phonemic contrast in Uyghur on the basis of a lack of acoustic and structural evidence

We propose that this behavior should be accounted for by lexical specification of root behavior

4. Experimental study

Participants: 23 native Uyghur speakers living in Almaty, KZ

Stimuli: 29 neutral roots elicited in unsuffixed and suffixed (LOC) form

Carrier phrase: Mahinur ______ deydu

Vowels segmented by hand, F2 extracted at vowel midpoint

5. Analysis of vowels in unsuffixed tokens

Fit linear-mixed effects model to data (refer to proceedings paper for detail about model)

Dependent variable F2 of final vowel

<table>
<thead>
<tr>
<th>Predictors</th>
<th>Predictors</th>
</tr>
</thead>
<tbody>
<tr>
<td>Suffix choice (F or B)</td>
<td>Gender</td>
</tr>
<tr>
<td>Place of following C</td>
<td>Place of following C</td>
</tr>
<tr>
<td>Random intercepts</td>
<td>Speaker Root</td>
</tr>
</tbody>
</table>

Place of following C predicts F2

- velar, lateral
- coronal, labial
- n/a, palatal

Suffix choice does not predict F2

The variation observed in F2 between roots cannot be attributed to their harmonic behavior.

6. Analysis of vowels in suffixed tokens

Suffix choice does not predict F2 in suffixed forms

No significant co-articulatory effects between suffix and preceding neutral vowel

7. Structural considerations

No minimal pairs exist between /i/ and /ɯ/

- i.e. no pairs like hypothetical */sɯp/ vs. */sip/

The /i/~/ɯ/ distinction has a functional load of 0

- Neutralizing contrast does not increase ambiguity (entropy)

Phonemic contrasts with a functional load of 0 can be learned based on phonetic dissimilarity (e.g. Peperkamp et al. 2006)

- E.g., /i/~/ɪ/ in English
- /i/ and /ɯ/ are not phonetically dissimilar

Structural evidence does not support a phonemic contrast

8. Discussion

No acoustic or structural evidence supports underlying contrast between /i/ and /ɯ/

- Corroborates later work on Hungarian (Bialio and Szeredi 2013) and smaller study on Uyghur (McCollum 2021)

Lexical diacritics are a simpler analysis (Mayer 2021)

- Unifies neutral roots with other exceptional roots
- Speakers learn front neutral roots as exceptions

Both analyses are descriptively adequate (Chomsky 1956)

- We should strive for explanatory adequacy
- Bring additional data to bear on analyses
- Consider learnability!
